Zulqarnain Hassan

Roll No: SP21379

Subject:Business Process Engineering

Department: BSSE-4-Afternoon

Date:09-03-2024

Success of any engineering and business operation depends on taking right decisions at the designing stage. The Ten critical decisions plays a pivotal role in optimizing production processes. These decisions guide us towards efficiency and effectiveness.

When we considered the Ten critical decisions in our business then the business will success and more productive in short time, and also reduce the chance of loss.

Managing QCD:

QCD stands for Quality, Cost and Delivery. These three things are the most important aspects that lead to a new business successful.

1) Quality:

When you are going to start a business that is similar to the business already exist in the market. So here you have to first look at the quality of the products that are delivering by the existing businesses in the market.

Identify the customers needs that still fail to delivered

by the existing businesses. So identify the unaddress needs. For example:

When the Daewoo Bus service first started their services in Pakistan then they ~~re~~ found that in the existing traveler there are some problems that facing by customer like time, cost, and convenient.

So they try to overcome these problem and they was success in that and ~~was~~ as a result the Daewoo success in their business in short time.

ii) Cost:

Cost ~~is~~ is and important factor because if you are selling a product which is no doubt good and you are fully facilitating customer with their need but the price in which you are selling your product is high; so your all quality measures will go in vain so you have to think about cost ^{of} your product would be cost effective.

For example:

If you are selling shirts although it has too many qualities but price is so high so people will not buy your product because they are getting the product in less price.

iii) Delivery:

The third thing is delivery. It is also important to consider because if you are fail to delivery your product then definitely you will loss everything. For example:

If you place your product on grocery store so people go there to buy their things frequently so if they need your product and they have seen so they can buy that too instead of going on special place to only take your product.

Goods and services:

In the design of goods and services we will see ~~what~~ which type of goods and services we should deliver.

Right design of goods affects the quality and cost.

Strive for consistency in cost, quality, and resource allocation across all business divisions. This ensures efficient production and delivery of goods and services.

Process and Capacity design:

Once we have design the goods and services then we

design processes for the product.

In process design we will see what processes will these products require and in what order.

Also considere the equipment and technology is necessary for these processes.

Location:

Once we have design good, processes and capacity then we ~~decided~~ decide where should we put the facility.

while selecting location we should considered ~~some~~ several things like raw material, utilities and human resources etc.

For Example:

I'm going to make a sugar mill, then obviously I have to ~~se~~ choose a right location so I will choose the location where raw material near to me as possible because raw material used in sugar mill is very difficult to transport because of huge amount.

Also I will consider utilities like gas, electricity, road infrastructure etc.

Layout design:

Layout design is also an important thing to design, an efficient layout design enhance productivity.

In layout design we optimize the placement of workstations, desks, and material flow.

We arrange the facilities in a good manner.

Human resources and job design:

Implement continuous improvement programs with regular reviews, provide continuous training for employees, and institute employee satisfaction programs to achieve success in this area.

Provide a reasonable work environment.

Supply-chain management:

Determine the best strategies to streamline, be cost effective, and to develop trusted partners.

⊗ Efficient design of supply chain management increases quality and also effect cost.
